# Effect of Fluorodecyl-POSS on Poly-(chlorotritluoroethylene) Surfaces

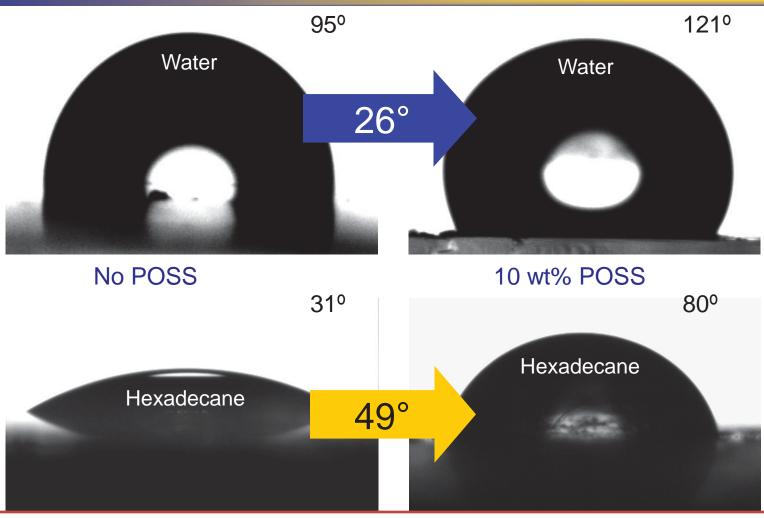

Significant improvements in repellence of both water and oil are seen when fluoro-POSS is added to PCTFE

### 10% FD POSS in 6F PFCB polymer

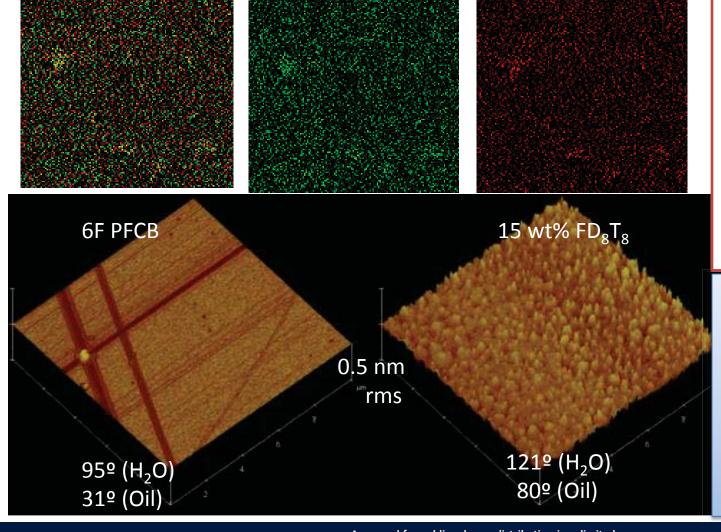

Another example of a fluoropolymer with liquid repellence improved by addition of fluoro-POSS, presumably due to the lower surface energy of Fluoro-POSS

Composite Blend

### **EDX/AFM of POSS/PFCB Surfaces**

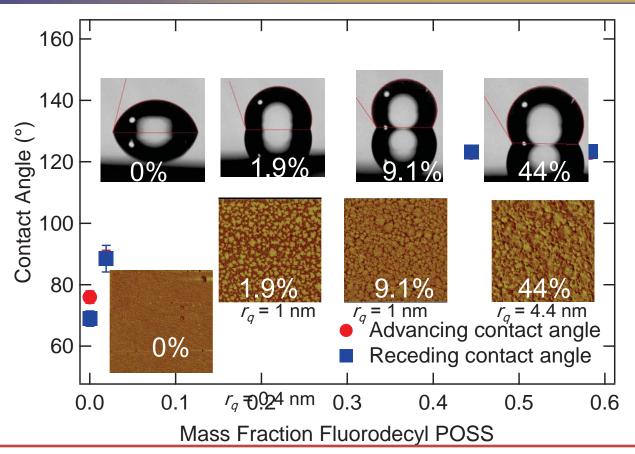

EDX shows that the surface becomes enriched in fluoro-POSS; AFM shows that surface migration alters the surface topography in addition to lowering surface energy.

The performance of fluoropolymers with added fluoro-POSS depends on both bulk (phase separation) and surface (migration) energies.

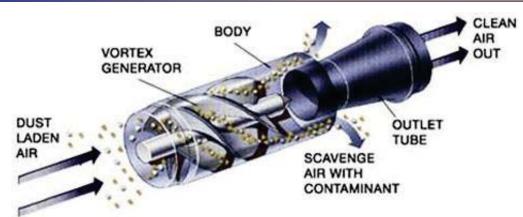

# POSS/PMMA: Spin coating smooth surfaces

Pure PMMA is hydrophilic, yet phase separation and surface migration drastically alter water repellence. Understanding both bulk and surface interactions between fluoro-POSS and polymers is the key to controlling performance. At present, a quantitative understanding of these phenomena is lacking.

# Controlled Surface Repellence Is an Important Enabler for AF Applications

Helicopter vortex tubes are used to exclude dust and contaminants from engine intakes. Requirements include light weight, ease of manufacturing, mechanical (structural / abrasion resistance), *fouling resistance*, and thermal performance.

The traditional material is a polypropylene that is highly filled to provide the required performance. The high filler loading makes manufacturing difficult due to the low thickness of part features (needed to save weight) that must be molded using a high viscosity material.

Inert POSS compounds, added as flow aids, allow more robust plastics such as cyclic olefin copolymers (COCs) to replace the polypropylene base material without sacrificing the ease of flow that facilitates ease of manufacturing. The high thermal stability and ~1 nm size of the POSS molecules provide the best available flow-enhancing characteristics and could also aid fouling resistance.

# **Bulk Interactions Can Be Quantified** through Hansen Solubility Parameters

ABSTRACT: The Hansen Solubity Parameters (HSP) for sexual polyhedral oligometic situagaiozane (POSS) ampounds was accomfully determined, demonstrating the applicability of the 1857 approach for substead types of organization-integratic compounds. As commonly nexticed with organize polymen, a set of simple "pauly split" tests for complete solubility is a fined communitation (100 mg/mil.) was conducted for an array of five outments POSS ampounds, ortic/pinestriply), odds/(prinestry). consistency, transfer an attention of the sign of the solvents that provided agraticantly enhanced solubility for octa/(sobutyl) POSS, and by successfully entimating the HSP of octabis/(trifluoropropyl) POSS from group contributions derived solidy from aromatic POSS compounds.

#### 1. INTRODUCTION

a Over the past few decades, Hansen Solubility Paremeters 39 (HSP) have achieved a high level of prominence in the coatings ndutry as a practical tool for estimating a writty of thermodynamic and transport properties in polymer sys-22 tems. 2-4 An advantage of the HSP approach over the simpler to one-component Hildebrand solubility parameter theory is that to the HSP approach enables the identification of mixtures of as noncolvents that, when combined in the proper ratio, become a good solvents for difficult to dissolve polymen. The adoption of the HSP approach to the more general problem of finding a sets of polymers and/or small-molecule fluids that display desired thermodynamic interaction characteristics, whether se favorable or unfavorable, has saved countless hours of total n and error in gas separation membranes, drug delivery? "and n nanocompostes!" applications. It is, therefore, vertually n certain that succaseful efforts streed at expanding the range of na applicability of Hannan Solubility Parameters will generate as numerous very substantial positive impacts across a wide variety

 $\pi$  Polyhedral oligometic stranquioxanes (POSS)<sup>16</sup> am a family se of inorganic/organic core/shell nanostructures possessing somelecular weight values on the order of 1000 g/mol, in so which the core consists of a silenquiozone cage with the  $\alpha$  formula (SiO<sub>10</sub>), where  $\alpha$  is generally between 8 and 14. The e shall consists of a organic functional groups originating at each et St atom on a cage vertex. Cages are generally categorized et according to the bonding type and number of silicon atoms that es comprise each vertex. The functionality may very from one e organic group to another, although the most commonly used e compounds feature octamente ages with identical, simple

Since their commercialization in the late 1990s, POSS a compounds have found a large variety of uses, particularly as so modifier for polymen and morganic files in the medical " si seroques, " and electronic industries," where they serve as p processing side for high-temperature thermoplastics, depends on and compatibilization agents, and thermal and electrical as insulation enhancers. The inorganic core is both mechanically as robust, resistant to oxidation, and thermally stable, and the w ability to synthesize a variety of peripheral groups makes the m tailoring of properties fairly straightforward. Double the many  $y_0$  applications for POSS compounds that involve thermodynamic mcompatibility and mixing, there have been few systematic or comparative attempts to quantify POSS solubility in common as organic solvents. <sup>30,33</sup>

More agraticant effort, however, has been devoted to exploring the solubility of inert POSS compounds in expolyment. 3415 There have been numerous reports of good es compatibility between certain POSS compounds and selected as polyment, e.g., octakie(2-phenylethyl), referred to as octa- or (phenethyl), POSS and either polystyrene or polystryl a chloride. However, in many cases, the reported solubility of # POSS compounds in polyment of interest is quite limited to Therefore, there is a clear need for a rational approach to n determine the solubility and thermodynamic interactions of a POSS compounds with both solvents and polymens.

Despite the obvious need, there has been only a small o amount of published work to date on the solubility parameters to of POSS compounds. Recent work reported by the Morgan of

Volume fractions

Knowledge of Hansen Solubility Parameters enables the computation of the enthalpy of mixing between two components. For polymers, the value of the enthalpy of mixing controls the rate and extent of phase separation.

When plotted in a 3-dimensional "solubility parameter space", good solvents (an indication of low enthalpy of mixing) tend to lie within a "sphere of solubility" centered on co-ordinates that correspond to the HSP of the solute. This "spherical rule" results from the similarity of the above equation to a geometric distance formula.

# Hansen Solubility Parameters for Polymer Systems

#### **Experimental method for determining HSP**

The traditional approach to estimating Hansen solubility parameters requires trials of typically 30 or 50 different solvents, but is straightforward to carry out. "Good" typically is indicated by >5% or 10% solubility, or by swelling, ESC, etc.

- Determine solubility (or affinity) in a large set of trial solvents
- Hansen solubility 2. Plot the HSP of "good" and "poor" parameters (HSP) solvents in a "solubility parameter space" as shown.
  - 3. "Good" solvents normally lie near one another in a "region of solubility"
  - 4. When  $2\delta_D$  is used as an axis, the region of solubility is typically bounded by a sphere.
  - 5. The center coordinates of the sphere mark the newly determined HSP.
  - 6. With knowledge of the HSP and "radius of interaction" (test dependent), test results for any subsequent solvent (or mixture) are reliably predicted.

21.6 mN(m) and methanol (y<sub>0</sub> = 22.7 mN(m), requires an appropriately chosen surface microhanotexture in addition to a low solid-surface energy (y<sub>0</sub>). 11, 113, 123, 231 Hepsadecallourodecy) polyhedral oligomeric silensquioxane (fluorodecy) POSS) offers one of the lowest solid surface energy values ever reported (y<sub>0</sub> ≈ 10 mN(m) and has become the molecule of choice for coating inclusive surfaces. In this work, we synthesize and evaluate a series of related molecules that either retain the POSS cage and delife in fluoroadsyl chain leight or that retain the Buomodexyl chains surrounding a linear or cyclic molecular structure. The solid surface energy  $(y_m)$  of these molecules was estimated using contact angle measurements on Bia spin-context silton wafer surfaces. Zaman analysis was performed using a hornologous series of n albanes (15.5 %  $p_n \le 27.5$  mW/m), whereas Girlisho—Cood analysis was performed using a set of polar and nonpolar liquids with a wider range of liquid surface tension (15.5  $\leq y_n \leq$  72.1 mWm). The hydrogen-bond-donating hydrogen-bond-accepting, polar, and nonpolar (dispension) contributions to the solid-surface energy of each compound were determined by probing the surfaces using a set of three liquid droplets of either acetone, chloroform, and do

KEYWORDS: superhydrophobicity • oleophobicity • solid surface energy • Zisman analysis • Girlfalco-Good method

In the recent past, there have been a number of reports on surfaces that are not wetted by liquid droplets, i.e., superhydrophobic (1-4), aleophobic (5-15), hygrophobic (16), and omniphobic (7, 12) surfaces. These surfaces have potential applications in oil-water separation, nonwettable textiles (2, 3, 6, 8, 9, 14, 15), and fingerprint/ smudge resistant touch-screen devices. Here we use the term omniphobicity to refer to surfaces that are not wetted by a broad set of liquids, including water, alkanes, alcohols, acids, bases, and other organic liquids. The design of omniphobic surfaces involves selection of a suitable surface chemistry to minimize the solid-surface energy and optimal

In our previous work, we emphasized re-entrant topography as a necessary condition for the design of surfaces that are not wetted by low-surface-tension liquids (7-9, 11-13). Liquids such as octane ( $y_b = 21.6 \text{ mN/m}$ ) and methanol ( $y_b$ 

cdu R.E.C.); genth@mit.cdu G.H.M.). Rescived for review August 13, 2010 and accepted October 21, 2010.

- 22.7 mN/m) will partially wet a flat untextured surface (equilibrium contact angle,  $\theta_c < 90^\circ$ ) of any surface chemistry. Using a combination of surface chemistry and reentrant texture, surfaces that exhibit substantially enhanced nonwettability to such liquids (apparent contact angle,  $\theta^*$  > 90°) can be created. On such nonwetting surfaces, liquid droplets sit partially on the solid texture and partially on the air trapped between the asperities of the solid texture. The Cassie-Baxter (CR) relation can be used to understand variations in the apparent contact angles (8°) for liquid droplets with solid-liquid-air composite interfaces. The CB relation shows that the apparent contact angle (0") increases as the equilibrium contact angle  $(\theta_0)$  increases and as the relative amount of trapped air increases (17). We have also developed an expression for the breakthrough pressure (PJ) required for the disruption of this solid-liquid-air compos ite interface (or "CB state") (12). Both the apparent contact angle ( $\theta$ \*) and the breakthrough pressure ( $P_{\lambda}$ ) increase monotonically with increasing equilibrium contact angle  $(\theta_{\bullet})$ (7-9, 12). Therefore, maximizing  $\theta_e$  is one objective in the optimal design of omniphobic surfaces with robust compos-

We have used fluorodecyl POSS-based coatings to design a range of robust nonwettable surfaces (7-9, 11-13). A fluorodecyl POSS molecule consists of a silicon-oxygen cage surrounded by eight 1H,1H,2H,2H-heptadecaffuorodecyl chains (18). A flat silicon wafer spin-coated with a uniform coating of this molecule has one of the highest reported values of equilibrium contact angle for water

# Relationships Between Surface and Bulk Properties

$$\gamma = 0.75 \, \delta^{4/3}$$

$$\gamma = [P_s / V(T)]^4; P_s \sim V_w$$

$$\gamma_{\rm D} = 4.79 \ \delta_{\rm D} - 51.87$$

A. Carré and J. Vial, *J. Adhesion*, **1995**, 42, 265.

- These relationships predict the properties of liquid surfaces, however, most fluorosilicates are solids at room temperature
- Even in liquids, molecular order at the surface is not taken into account by the predicted values
- To date, no widely known correlations exist for polar and hydrogen bonding components
- In general, hydrogen bonding is much stronger in bulk than at the surface (perhaps due to fewer constraints on interlocking in the bulk)

Hexafluoroi-i-butyl T8	43.5	21.4
Fluorodecyl M2	34.6	24.8

- For perfluoroheptane, the predicted value of  $\gamma_{lv}$  of 21 dyn/cm is close to expectations
- Agreement for the dispersive component is better, but  $\gamma^{d}_{lv} < \gamma_{lv}$  without rearrangement

## Application to Miscibility and Phase **Separation**

$$\frac{\partial \phi(r,t)}{\partial t} = -\nabla J(r,t) + \eta(r,t)$$

$$J(r) = -M\nabla \mu(r)$$

$$\mu = \frac{\delta G}{\delta \phi} = \frac{\partial G}{\partial \phi} - \nabla \frac{\partial G}{\partial \nabla \phi} \qquad \kappa = \frac{1}{36} \left(\frac{a_1^2}{\phi} + \frac{a_2^2}{1-\phi}\right)$$

$$\frac{\Delta G}{k_B T} = \int_{\Gamma} \left(f \left[\phi(r)\right] + \kappa \left[\nabla \phi(r)\right]^2\right) dV$$

The Time-Dependent Ginzburg-Landau equation (linearized to Cahn-Hilliard equation) represents the established mathematical framework for predicting phase separation, if you know the " $\chi$ " parameter

$$\frac{\partial \phi(r,t)}{\partial \phi(r,t)} = M\nabla^2 \frac{\partial G}{\partial t} + n(r,t)$$

$$\chi = V_{ref}[(\delta_{D1} - \delta_{D2})^2 + (1/4) (\delta_{P1} - \delta_{P2})^2 +$$

$$\frac{\partial \phi(r,t)}{\partial \phi(r,t)} = M\nabla^2 \begin{cases} \frac{\ln \phi + 1}{N_1} - \frac{\ln(1-\phi) + 1}{N_2} + \chi(1-2\phi) \\ \frac{\partial \phi(r,t)}{\partial \phi(r,t)} = \frac{1}{N_2} \frac{\ln \phi + 1}{N_2} - \frac{\ln(1-\phi) + 1}{N_2} + \chi(1-2\phi) \end{cases}$$

$$(1/4)(\delta_{H1} - \delta_{H2})^2$$

 $\frac{\partial \phi(r,t)}{\partial t} = M \nabla^2 \frac{\delta G}{\delta \phi} + \eta(r,t)$ As an example, for octaphenethyl-POSS in PEI:  $\frac{\partial \phi(r,t)}{\partial t} = M \nabla^2 \begin{cases} \frac{\ln \phi + 1}{N_1} - \frac{\ln(1-\phi) + 1}{N_2} + \chi(1-2\phi) \\ -\frac{1}{18} \left(\frac{a_1^2}{\phi} + \frac{a_2^2}{1-\phi}\right) \nabla^2 \phi + \frac{1}{36} \left(\frac{a_1^2}{\phi^2} - \frac{a_2^2}{(1-\phi)^2}\right) (\nabla \phi)^2 \end{cases}$   $\frac{\partial \phi(r,t)}{\partial t} = M \nabla^2 \begin{cases} \frac{\ln \phi + 1}{N_1} - \frac{\ln(1-\phi) + 1}{N_2} + \chi(1-2\phi) \\ -\frac{1}{18} \left(\frac{a_1^2}{\phi} + \frac{a_2^2}{1-\phi}\right) \nabla^2 \phi + \frac{1}{36} \left(\frac{a_1^2}{\phi^2} - \frac{a_2^2}{(1-\phi)^2}\right) (\nabla \phi)^2 \end{cases}$   $\frac{\partial \phi(r,t)}{\partial t} = M \nabla^2 \begin{cases} \frac{\ln \phi + 1}{N_1} - \frac{\ln(1-\phi) + 1}{N_2} + \chi(1-2\phi) \\ -\frac{1}{18} \left(\frac{a_1^2}{\phi} + \frac{a_2^2}{1-\phi}\right) \nabla^2 \phi + \frac{1}{36} \left(\frac{a_1^2}{\phi^2} - \frac{a_2^2}{(1-\phi)^2}\right) (\nabla \phi)^2 \end{cases}$   $\frac{\partial \phi(r,t)}{\partial t} = M \nabla^2 \begin{cases} \frac{\ln \phi + 1}{N_1} - \frac{\ln(1-\phi) + 1}{N_2} + \chi(1-2\phi) \\ -\frac{1}{18} \left(\frac{a_1^2}{\phi} + \frac{a_2^2}{1-\phi}\right) \nabla^2 \phi + \frac{1}{36} \left(\frac{a_1^2}{\phi^2} - \frac{a_2^2}{(1-\phi)^2}\right) (\nabla \phi)^2 \end{cases}$   $\frac{\partial \phi(r,t)}{\partial t} = M \nabla^2 \begin{cases} \frac{\ln \phi + 1}{N_1} - \frac{\ln(1-\phi) + 1}{N_2} + \chi(1-2\phi) \\ \frac{\partial \phi(r,t)}{\partial t} - \frac{\partial \phi(r,t)}{\partial t} + \frac{\partial \phi(r,t)}{\partial t} - \frac{\partial \phi(r,t)}{\partial t} \end{cases}$   $\frac{\partial \phi(r,t)}{\partial t} = M \nabla^2 \begin{cases} \frac{\ln \phi + 1}{N_1} - \frac{\ln(1-\phi) + 1}{N_2} + \chi(1-2\phi) \\ \frac{\partial \phi(r,t)}{\partial t} - \frac{\partial \phi(r,t)}{\partial t} - \frac{\partial \phi(r,t)}{\partial t} \end{cases}$   $\frac{\partial \phi(r,t)}{\partial t} = M \nabla^2 \begin{cases} \frac{\ln \phi + 1}{N_1} - \frac{\ln(1-\phi) + 1}{N_2} + \chi(1-2\phi) \\ \frac{\partial \phi(r,t)}{\partial t} - \frac{\partial \phi(r,t)}{\partial t} - \frac{\partial \phi(r,t)}{\partial t} \end{cases}$   $\frac{\partial \phi(r,t)}{\partial t} = M \nabla^2 \begin{cases} \frac{\ln \phi + 1}{N_1} - \frac{\ln(1-\phi) + 1}{N_2} + \chi(1-2\phi) \\ \frac{\partial \phi(r,t)}{\partial t} - \frac{\partial \phi(r,t)}{\partial t} - \frac{\partial \phi(r,t)}{\partial t} \end{cases}$   $\frac{\partial \phi(r,t)}{\partial t} = M \nabla^2 \begin{cases} \frac{\ln \phi + 1}{N_1} - \frac{\ln(1-\phi) + 1}{N_2} + \frac{\ln(1-\phi) + 1}{N_2} + \frac{\ln(1-\phi) + 1}{N_2} + \frac{\ln(1-\phi) + 1}{N_2} + \frac{\ln(1-\phi) + 1}{N_2} \end{cases}$   $\frac{\partial \phi(r,t)}{\partial t} = M \nabla^2 \begin{cases} \frac{\partial \phi(r,t)}{\partial t} + \frac{\partial \phi(r,t)}{\partial t}$ 

As an example, for octa-

 $N_1 = 10$ ;  $N_2 = 100$ 

Predicted miscibility: 10-20%

Actual miscibility: 2.6%

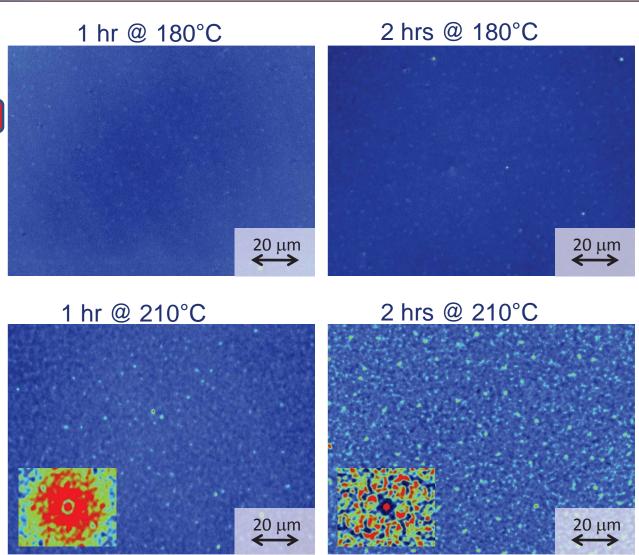

### Surface Migration of 5 wt% Octa-Phenethyl POSS in PEI

Surface Height Map 0 nm 50 nm

Films annealed at 180°C show effects that are not significantly different from those seen in pure PEI. At 210°C, fine aggregates and, later, a phase separated texture appear. The insets show the autocovariance (same length scale as main figure, red = high) of the pattern for annealing at 210°C, indicating periodicity.

### **Future Work**

- Determine Hansen solubility parameters for additional silicate types ("D" is available from polysiloxanes, "T" from POSS, more "M" and "Q" examples needed)
- Improve precision of group contribution values for POSS cages and other silicate structures, as well as for fluorocarbons

 Generate additional predictions of miscibility and develop a spatiotemporal model for surface migration of silicate additives

 Use controlled migration to design organic / inorganic hybrids with optimal liquid repellence and other desirable properties

### **Summary**

- Controlling the liquid repellence characteristics of polymer / silicate nanocomposites requires quantitative knowledge of both bulk and surface thermodynamic parameters.
- Quantitative surface and bulk thermodynamic data for polymer / silicate nanocomposites (including fluorinated polymers and fluoro-POSS) has recently become available.
- Comparisons of surface and bulk thermodynamic parameters provide insight into the nature of the silicate / polymer nanocomposite surface
- Application of the thermodynamic data to investigate miscibility and phase separation in polymer / silicate nanocomposites is underway
